Dynamical Systems

1. Consider the recurrence relation

$$x_{n+2} = \frac{7}{16}x_n + \frac{3}{2}x_{n+1} + x_n^2,$$

where  $x_i \in \mathbb{R}$  ( $i = 0, 1, 2, \dots$ ).

- Find the fixed points of this recurrence relation.
- Determine the nature of the fixed point at the  $(x, y)$  origin of the corresponding  $\mathbb{R}^2$  system in which  $y_n = x_{n+1}$ .
- Give the definitions of the stable and unstable subspaces of the origin.
- Let  $\begin{pmatrix} 1 \\ \alpha \end{pmatrix}$  and  $\begin{pmatrix} 1 \\ \beta \end{pmatrix}$  be vectors aligned with the stable and unstable subspaces, respectively. Find the constants  $\alpha$  and  $\beta$ , and write down the equations of the stable and unstable subspaces.
- Introduce the vector  $\begin{pmatrix} u_n^+ \\ u_n^- \end{pmatrix}$  which is defined via

$$\begin{pmatrix} x_n \\ y_n \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ \alpha & \beta \end{pmatrix} \begin{pmatrix} u_n^+ \\ u_n^- \end{pmatrix}.$$

Thereby, show that the system may be expressed in the form

$$\begin{aligned} u_{n+1}^+ &= c_1 u_n^+ + c_2 (u_n^+)^2 + c_3 (u_n^+ u_n^-) + c_4 (u_n^-)^2, \\ u_{n+1}^- &= d_1 u_n^- + d_2 (u_n^+)^2 + d_3 (u_n^+ u_n^-) + d_4 (u_n^-)^2; \end{aligned}$$

and evaluate the constants  $c_{1,\dots,4}$  and  $d_{1,\dots,4}$ .

- State the stable manifold theorem.
- Find the quadratic approximations to the stable and unstable manifolds in the  $(u^+, u^-)$  plane.
- Sketch the stable and unstable manifolds in the  $(u^+, u^-)$  plane. Include in your sketch a few representative orbits and identify the stable and unstable subspaces.

**Solution.**

- (a) The fixed points  $x = x^*$  satisfy

$$x^* = \frac{7}{16}x^* + \frac{3}{2}x^* + (x^*)^2 \quad \text{i.e.,} \quad x^* \left( x^* + \frac{15}{16} \right) = 0$$

so we have  $x^* = 0$  and  $x^* = -15/16$ .

- (b) We have

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \mathbf{F} \begin{pmatrix} x_n \\ y_n \end{pmatrix} = \begin{pmatrix} y_n \\ \frac{7}{16}x_n + \frac{3}{2}y_n + x_n^2 \end{pmatrix}.$$

The Jacobian matrix:

$$D\mathbf{F} = \begin{pmatrix} 0 & 1 \\ \frac{7}{16} + 2x_n & \frac{3}{2} \end{pmatrix} \quad \Rightarrow \quad D\mathbf{F}|_{\mathbf{0}} = \begin{pmatrix} 0 & 1 \\ \frac{7}{16} & \frac{3}{2} \end{pmatrix} = A.$$

The eigenvalues  $\lambda = \lambda_{1,2}$  of  $A$  are given by

$$(0 - \lambda) \left( \frac{3}{2} - \lambda \right) - \frac{7}{16} = 0, \quad \text{i.e.,} \quad \left( \lambda - \frac{7}{4} \right) \left( \lambda + \frac{1}{4} \right) = 0;$$

thus, we have  $\lambda_1 = -1/4$  and  $\lambda_2 = 7/4$ . Since  $|\lambda_1| < 1$  and  $|\lambda_2| > 1$ , the fixed point at  $x = 0, y = 0$  is a saddle point.

- (c) The stable subspace  $E^+$  is the span of eigenvectors associated with eigenvalues  $\lambda$  with  $|\lambda| < 1$ . The unstable subspace  $E^-$  is the span of eigenvectors associated with eigenvalues  $\lambda$  with  $|\lambda| > 1$ .
- (d) The eigenvector  $\begin{pmatrix} e_{x1} \\ e_{y1} \end{pmatrix}$  associated with  $\lambda_1$  is given via

$$\begin{pmatrix} 0 & 1 \\ \frac{7}{16} & \frac{3}{2} \end{pmatrix} \begin{pmatrix} e_{x1} \\ e_{y1} \end{pmatrix} = -\frac{1}{4} \begin{pmatrix} e_{x1} \\ e_{y1} \end{pmatrix}, \quad \text{i.e.,} \quad \begin{pmatrix} e_{x1} \\ e_{y1} \end{pmatrix} = \begin{pmatrix} 1 \\ -\frac{1}{4} \end{pmatrix}, \text{ say;}$$

and the eigenvector  $\begin{pmatrix} e_{x2} \\ e_{y2} \end{pmatrix}$  associated with  $\lambda_2$  is given via

$$\begin{pmatrix} 0 & 1 \\ \frac{7}{16} & \frac{3}{2} \end{pmatrix} \begin{pmatrix} e_{x2} \\ e_{y2} \end{pmatrix} = \frac{7}{4} \begin{pmatrix} e_{x2} \\ e_{y2} \end{pmatrix}, \quad \text{i.e.,} \quad \begin{pmatrix} e_{x2} \\ e_{y2} \end{pmatrix} = \begin{pmatrix} 1 \\ \frac{7}{4} \end{pmatrix}, \text{ say.}$$

Hence,  $E^+$  is the line  $y = -\frac{1}{4}x$ , and  $E^-$  is the line  $y = \frac{7}{4}x$ .

- (e) We have  $S = \begin{pmatrix} 1 & 1 \\ -\frac{1}{4} & \frac{7}{4} \end{pmatrix}$  with

$$\begin{pmatrix} u_n^+ \\ u_n^- \end{pmatrix} = \frac{1}{2} \begin{pmatrix} \frac{7}{4} & -1 \\ \frac{1}{4} & 1 \end{pmatrix} \begin{pmatrix} x_n \\ y_n \end{pmatrix} = \frac{1}{2} \begin{pmatrix} \frac{7}{4}x_n - y_n \\ \frac{1}{4}x_n + y_n \end{pmatrix} \quad (1)$$

and

$$\begin{pmatrix} x_n \\ y_n \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ -\frac{1}{4} & \frac{7}{4} \end{pmatrix} \begin{pmatrix} u_n^+ \\ u_n^- \end{pmatrix} = \begin{pmatrix} u_n^+ + u_n^- \\ -\frac{1}{4}u_n^+ + \frac{7}{4}u_n^- \end{pmatrix}. \quad (2)$$

Now, using eqn (1), we can re-write  $x_{n+1} = y_n$  as

$$u_{n+1}^+ + u_{n+1}^- = -\frac{1}{4}u_n^+ + \frac{7}{4}u_n^-; \quad (3)$$

and, using eqn (2), we can re-write  $y_{n+1} = \frac{7}{16}x_n + \frac{3}{2}y_n + x_n^2$  as

$$\begin{aligned} -\frac{1}{4}u_{n+1}^+ + \frac{7}{4}u_{n+1}^- &= \frac{7}{16}(u_n^+ + u_n^-) + \frac{3}{2}\left(-\frac{1}{4}u_n^+ + \frac{7}{4}u_n^-\right) + (u_n^+ + u_n^-)^2 \\ &= \frac{1}{16}u_n^+ + \frac{49}{16}u_n^- + (u_n^+ + u_n^-)^2. \end{aligned} \quad (4)$$

Taking  $\frac{7}{4}(3) - (4)$  gives:

$$\begin{aligned} 2u_{n+1}^+ &= -\frac{7}{16}u_n^+ + \frac{49}{16}u_n^- - \frac{1}{16}u_n^+ - \frac{49}{16}u_n^- - (u_n^+ + u_n^-)^2 \\ \text{i.e., } u_{n+1}^+ &= -\frac{1}{4}u_n^+ - \frac{1}{2}(u_n^+ + u_n^-)^2; \end{aligned} \quad (5)$$

i.e., we have  $c_1 = -\frac{1}{4}$ ,  $c_2 = -\frac{1}{2}$ ,  $c_3 = -1$  and  $c_4 = -\frac{1}{2}$ .

Similarly, taking  $\frac{1}{4}(3) + (4)$  gives:

$$\begin{aligned} 2u_{n+1}^- &= -\frac{1}{16}u_n^+ + \frac{7}{16}u_n^- + \frac{1}{16}u_n^+ + \frac{49}{16}u_n^- + (u_n^+ + u_n^-)^2 \\ \text{i.e., } u_{n+1}^- &= \frac{7}{4}u_n^- + \frac{1}{2}(u_n^+ + u_n^-)^2; \end{aligned} \quad (6)$$

i.e., we have  $d_1 = \frac{7}{4}$ ,  $d_2 = \frac{1}{2}$ ,  $d_3 = 1$  and  $d_4 = \frac{1}{2}$ .

- (f) The stable manifold theorem asserts the existence of (i) an invariant stable manifold  $W^s$  defined by  $\{\mathbf{x} : \mathbf{F}^k(\mathbf{x}) \rightarrow \mathbf{0} \text{ as } k \rightarrow \infty\}$ ; and (ii) an invariant unstable manifold  $W^u$  defined by  $\{\mathbf{x} : \mathbf{F}^k(\mathbf{x}) \rightarrow \mathbf{0} \text{ as } k \rightarrow -\infty\}$ .
- (g) Consider the quadratic expansion of the stable manifold:  $u^- = a_2(u^+)^2$ . We have

$$\begin{aligned} u_{n+1}^- &= a_2(u_{n+1}^+)^2 \\ &= a_2 \left[ -\frac{1}{4}u_n^+ - \frac{1}{2}(u_n^+ + u_n^-)^2 \right]^2 && \text{from eqn (5)} \\ &= a_2 \left[ \frac{1}{16}(u_n^+)^2 + \frac{1}{4}u_n^+(u_n^+ + u_n^-)^2 + \frac{1}{4}(u_n^+ + u_n^-)^4 \right] \\ &\approx a_2 \frac{1}{16}(u_n^+)^2 && \text{(neglecting cubic and higher-order terms).} \end{aligned} \quad (7)$$

Also, recalling eqn (6), we have

$$\begin{aligned} u_{n+1}^- &= \frac{7}{4}a_2 (u_n^+)^2 + \frac{1}{2} \left[ u_n^+ + a_2 (u_n^+)^2 \right]^2 \\ &\approx \left( \frac{7}{4}a_2 + \frac{1}{2} \right) (u_n^+)^2 \quad \text{(neglecting cubic and higher-order terms).} \end{aligned} \quad (8)$$

Comparing eqns (7) and (8), we find

$$a_2 \frac{1}{16} = \frac{7}{4}a_2 + \frac{1}{2}, \quad \text{i.e.,} \quad a_2 = -\frac{8}{27}.$$

Consider the quadratic expansion of the unstable manifold:  $u^+ = b_2 (u^-)^2$ . We have

$$\begin{aligned} u_{n+1}^+ &= b_2 (u_{n+1}^-)^2 \\ &= b_2 \left[ \frac{7}{4}u_n^- + \frac{1}{2} (u_n^+ + u_n^-)^2 \right]^2 \quad \text{from eqn (6)} \\ &= b_2 \left[ \frac{49}{16} (u_n^-)^2 + \frac{7}{4}u_n^- (u_n^+ + u_n^-)^2 + \frac{1}{4} (u_n^+ + u_n^-)^4 \right] \\ &\approx b_2 \frac{49}{16} (u_n^-)^2 \quad \text{(neglecting cubic and higher-order terms).} \end{aligned} \quad (9)$$

Also, recalling eqn (5), we have

$$\begin{aligned} u_{n+1}^+ &= -\frac{1}{4}b_2 (u_n^-)^2 - \frac{1}{2} \left[ u_n^- + b_2 (u_n^-)^2 \right]^2 \\ &\approx \left( -\frac{1}{4}b_2 - \frac{1}{2} \right) (u_n^-)^2 \quad \text{(neglecting cubic and higher-order terms).} \end{aligned} \quad (10)$$

Comparing eqns (9) and (10), we find

$$b_2 \frac{49}{16} = -\frac{1}{4}b_2 - \frac{1}{2}, \quad \text{i.e.,} \quad b_2 = -\frac{8}{53}.$$

(h) Sketch see figure 1:

Figure 1: Stable and unstable manifolds.

2. Consider the mapping  $x_{n+1} = G(x_n)$  with

$$G(x) = 2\pi \sin x,$$

for  $x \in [0, \pi]$ .

- Let  $I_1 = [0, a]$  and  $I_2 = [b, \pi]$  with  $a < b$ . Find the largest value of  $a$  and smallest value of  $b$  such that  $G$  maps  $I_1 \cup I_2$  onto  $[0, \pi]$ .
- Briefly discuss the stability of the fixed points of  $G$ .  
(You are not required to locate exactly the fixed points).
- Describe the invariant set  $S = \{x \in [0, \pi] : G^k(x) \in [0, \pi], k \in \mathbb{N}\}$  in terms of  $I_1$  and  $I_2$ .
- Give the definition of the itinerary map which forms the basis of the symbolic dynamics on  $S$  for  $G(x)$ .
- Show that the itinerary map is
  - surjective (the *Nested Intervals Theorem* may be assumed);
  - injective.
- How many prime period-6 orbits for  $G$  are in  $S$ ?  
How many prime period-8 orbits for  $G$  are in  $S$ ?  
Justify your answers.

(g) Show that the Liapunov exponent  $\lambda$  for  $G$  acting on  $S$  has the lower bound

$$\lambda \geq \ln \pi + \frac{\ln 3}{2}.$$

What can you infer from this?

**Solution.**

(a)  $\sin \frac{\pi}{6} = \sin \frac{5\pi}{6} = \frac{1}{2} \quad \Rightarrow \quad a = \frac{\pi}{6} \quad \text{and} \quad b = \frac{5\pi}{6}$

Figure 2: Graph of  $G(x) = 2\pi \sin(x)$ .

(b) From the sketch (see figure 2) there are two fixed points:  $x_i = 0$  and  $x_{ii} \in (\frac{5\pi}{6}, \pi)$ .

$$G'(0) = 2\pi \cos 0 = 2\pi \Rightarrow |G'(x_i)| > 1$$

$$\Rightarrow x_i \text{ is unstable}$$

$$G'(\frac{5\pi}{6}) = 2\pi \cos \frac{5\pi}{6} = -\sqrt{3}\pi \Rightarrow |G'(\frac{5\pi}{6})| > 1$$

$$G'(\pi) = 2\pi \cos \pi = -2 \Rightarrow |G'(\pi)| > 1$$

and  $G$  is strictly decreasing on  $(\frac{5\pi}{6}, \pi)$   $\Rightarrow x_{ii}$  is unstable

(c) Construct the sets:

$$I_{j_0 j_1 j_2 \dots j_n} = \{x : x \in I_{j_0} \text{ and } G^k(x) \in I_{j_k} \text{ for } 1 \leq k \leq n\}$$

where  $j_k = 1$  or  $2$ ; and

$$S_n = \bigcup_{j_0, j_1, \dots, j_n} I_{j_0 j_1 j_2 \dots j_n}.$$

Then, the invariant set is given by  $S = \bigcap_{n=0}^{\infty} S_n$ .

- (d) The symbolic dynamics are constructed via the itinerary map  $h : S \rightarrow \Sigma$  where  $\Sigma = \{1, 2\}^{\mathbb{N}}$  (i.e.,  $\Sigma$  is the set of all sequences of the symbols '1' and '2') and

$$h(x) = (j_0, j_1, j_2, \dots) \quad \text{with} \quad x_0 \in I_{j_0} \quad \text{and} \quad G^k(x) \in I_{j_k}.$$

- (e) i. Consider the sequence of symbols  $(j_0, j_1, j_2, \dots) \in \Sigma$ . Form the sequence of sets  $J_n = I_{j_0 j_1 j_2 \dots j_n}$ . Since the  $J_n$  form a nested family of closed intervals, by the Nested Intervals Theorem,  $\exists x^* \in \bigcap_{n=0}^{\infty} J_n$ . Thus,  $h(x^*) = (j_0, j_1, j_2, \dots)$ ; i.e.,  $h$  is surjective.
- ii. Observe that for  $x \in S$  we have

$$|G'(x)| = |2\pi \cos x| \geq |2\pi \cos \frac{\pi}{6}| > 1.$$

Therefore,  $|(G^k)'(x)| > 1$  in  $S$ , since  $(G^n)'(x_0) = \prod_{i=0}^{n-1} G'(x_i)$ .

Suppose there exists  $x, y \in S$  and  $h(x) = h(y)$ . This implies that  $G^k(x)$  and  $G^k(y)$  are in the same subinterval  $I_{j_0 j_1 j_2 \dots j_k}$  of the pair  $I_1 \cup I_2$ . From  $|G'| \geq q > 1$ , we have that

$$\begin{aligned} \left| \frac{G^{k+1}(y) - G^{k+1}(x)}{G^k(y) - G^k(x)} \right| &\geq q \\ \text{i.e.,} \quad |G^{k+1}(y) - G^{k+1}(x)| &\geq q |G^k(y) - G^k(x)| \\ &\geq q^2 |G^{k-1}(y) - G^{k-1}(x)| \\ &\geq q^3 |G^{k-2}(y) - G^{k-2}(x)| \\ &\vdots \\ &\geq q^{k+1} |y - x|. \end{aligned}$$

But  $|G^{k+1}(y) - G^{k+1}(x)| \leq 1$  (since  $x, y \in S$ ). So

$$|y - x| \leq \frac{1}{q^{k+1}}$$

which implies that  $x = y$ . Hence,  $h$  is injective.

- (f) Since  $h$  is bijective, a  $k$ -periodic orbit of  $G$  corresponds to a fixed point of  $\sigma^k$

where  $\sigma$  is the backward shift map.

$$\begin{aligned} \text{no. of prime period-6 orbits of } G &= \frac{1}{6} \left( \text{no. of fixed points of } \sigma^6 - \text{no. of fixed points of } \sigma^3 \right. \\ &\quad \left. - \text{no. of fixed points of } \sigma^2 + \text{no. of fixed points of } \sigma \right) \\ &= \frac{2^6 - 2^3 - 2^2 + 2}{6} = 9. \end{aligned}$$

$$\begin{aligned} \text{no. of prime period-8 orbits of } G &= \frac{1}{8} \left( \text{no. of fixed points of } \sigma^8 - \text{no. of fixed points of } \sigma^4 \right) \\ &= \frac{2^8 - 2^4}{8} = 30. \end{aligned}$$

(g) For  $x \in S$  we have

$$|G'(x)| \geq |G'(\frac{\pi}{6})| = \pi\sqrt{3}.$$

Therefore, Liapunov exponent

$$\lambda = \lim_{n \rightarrow \infty} \left\{ \frac{1}{n} \sum_{i=0}^{n-1} \ln |G'(x_i)| \right\} \geq \ln(\pi\sqrt{3}) \lim_{n \rightarrow \infty} \left\{ \frac{1}{n} \sum_{i=0}^{n-1} 1 \right\} = \ln(\pi\sqrt{3}) = \ln \pi + \frac{1}{2} \ln 3;$$

Since  $\lambda > 0$ , there is a sensitive dependency upon initial conditions.

3. (a) Prove that if a continuous  $\mathbb{R}^1$  mapping has a period-3 orbit then it has prime period- $n$  orbits for all  $n \in \mathbb{N}$ . (The *Intermediate Value Theorem* may be assumed).
- (b) Consider the  $\mathbb{R}^1$  mapping  $x_{n+1} = H_\mu(x_n)$  where

$$H_\mu(x) = \mu \left( \frac{1}{2} - \left| x - \frac{1}{2} \right| \right),$$

and  $\mu > 0$ .

- i. For both  $\mu > 1$  and  $\mu < 1$ , find the fixed points of  $H_\mu(x)$  and discuss their stability.
- ii. Let  $\mu = 2$ .
  - A. Find the orbit which starts at  $x_0 = 2/7$ .  
What can you infer from this?
  - B. By considering the graph of the iterated map  $H_2 \circ H_2$  or otherwise, find a period-2 orbit.

**Solution.**

- (a) Suppose the mapping  $H$  has the period-3 orbit  $\{a, b, c\}$ . WLOG we assume  $a < b < c$ . To prove that  $H$  has period- $n$  orbits for all  $n \in \mathbb{N}$ :

Let us define  $I_0 = [a, b]$  and  $I_1 = [b, c]$  and make the following observations

- i.  $H(I_0) \supseteq I_1$ .
- ii.  $H(I_1) \supseteq I_0 \cup I_1$ .
- iii. If  $I$  is a closed interval and  $H(I) \supseteq I$ , then  $H$  has a fixed point in  $I$ .
- iv. Suppose  $I, J$  are closed intervals. If  $H(I) \supseteq J$ , then there exists a closed interval  $K \subseteq I$  such that  $H(K) = J$ .

The last two observations can be established using the intermediate value theorem.

- We start by noting that (ii) and (iii) imply that  $H$  has a fixed point in  $I_1$ . Also, (i), (ii) and (iii) imply that  $H^2$  has a fixed point in  $I_0$ , so that  $H$  has a period-2 orbit. Thus, the period-1 and period-2 cases are proven.
- We have  $n > 3$ . Now we construct a nested sequence of closed intervals  $A_n$ : let  $A_0 = I_1$ , (ii) and (iv) imply that there is a  $A_1 \subseteq A_0$  with  $H(A_1) = A_0 = I_1$ . Similarly, there is a  $A_2 \subseteq A_1$  with  $H(A_2) = A_1$  and so  $H^2(A_2) = A_0$ . Proceeding similarly, the sequence

$$A_0 \supseteq A_1 \supseteq A_2 \supseteq \cdots \supseteq A_{n-2}, \quad \text{with} \quad H^k(A_k) = A_0, \quad k = 1, 2, \dots, n-2,$$

can be constructed. The next interval in the sequence,  $A_{n-1}$  is constructed by noting that  $H^{n-1}(A_{n-2}) = H(A_0) \supseteq I_0$  (using (ii)). Then, (iv) implies that there is a  $A_{n-1} \subseteq A_{n-2}$  with  $H^{n-1}(A_{n-1}) = I_0$ . Finally since  $H^n(A_{n-1}) = H(I_0) \supseteq I_1$  (using (i)), there exists a  $A_n \subseteq A_{n-1}$  with  $H^n(A_n) = A_0 = I_1$ . Now, by construction  $A_n \subseteq A_0$ , so that  $H^n(A_n) \supseteq A_n$ . So (iii) then implies that there exists a fixed point  $x^* \in A_n$  with  $H^n(x^*) = x^*$ . This is a prime period- $n$  point unless it is also fixed point of  $H^k$  for  $k < n$ . But this is impossible since  $x^* \in A_k$ ,  $k = 0, 1, \dots, n$  gives that  $H^k(x^*) \in I_1$  for  $k = 1, 2, \dots, n-2$  and we also have  $H^{n-1}(x^*) \in I_0$ . (The case  $H^{n-1}(x^*) \in I_0 \cap I_1 = \{b\}$  can be excluded since it would imply  $n = 3$ .)

- (b) i.

$$H_\mu(x) = \begin{cases} \mu x, & \text{for } x \leq \frac{1}{2} \\ \mu(1-x), & \text{for } x > \frac{1}{2} \end{cases}$$

Sketch see figure 3.

- For  $x \leq \frac{1}{2}$ :  
Fixed points satisfy  $x^* = \mu x^*$ , so for  $\mu < 1$  and  $\mu > 1$  we have the fixed point  $x^* = 0$ .  $G'_\mu(x) = \mu$  so  $x^*$  is stable for  $\mu < 1$  and unstable for  $\mu > 1$ .

Figure 3: Graph of  $H_\mu$  with  $\mu = 2$ .

- For  $x > \frac{1}{2}$ :  
Fixed points satisfy  $x^* = \mu(1 - x^*)$ ; i.e.,  $x^* = \frac{\mu}{1+\mu}$ . But  $x^* > \frac{1}{2}$  so we require that  $\frac{\mu}{1+\mu} > \frac{1}{2}$ ; i.e.,  $\mu > 1$ . Since  $G'_\mu(x) = -\mu$  the fixed point  $x^* = \frac{\mu}{1+\mu}$  is unstable.

ii. A. Let  $\mu = 2$ . Consider  $x_0 = \frac{2}{7}$ . Then

$$x_1 = H_\mu(x_0) = 2 \left( \frac{1}{2} - \left| \frac{2}{7} - \frac{1}{2} \right| \right) = \frac{4}{7}$$

and 
$$x_2 = H_\mu(x_1) = 2 \left( \frac{1}{2} - \left| \frac{4}{7} - \frac{1}{2} \right| \right) = \frac{6}{7}$$

and 
$$x_3 = H_\mu(x_2) = 2 \left( \frac{1}{2} - \left| \frac{6}{7} - \frac{1}{2} \right| \right) = \frac{2}{7}$$

i.e., 
$$x_0 = x_3.$$

Therefore there is a period-3 orbit  $\left\{ \frac{2}{7}, \frac{4}{7}, \frac{6}{7} \right\}$ .

By (a),  $H_2$  has period- $n$  orbits for all  $n \in \mathbb{N}$ .

B. Consider the iterated map  $(H_2 \circ H_2)(x)$  (sketch see figure 4):

- For  $x \leq \frac{1}{2}$ :

$$H_2(H_2(x)) = \begin{cases} 2 \times 2x, & \text{provided } 2x \leq \frac{1}{2} \\ 2(1 - 2x), & \text{provided } 2x > \frac{1}{2} \end{cases}$$

Figure 4:

- For  $x > \frac{1}{2}$ :

$$H_2(H_2(x)) = \begin{cases} 2 \times 2(1-x), & \text{provided } 2(1-x) \leq \frac{1}{2} \\ 2(1-2(1-x)), & \text{provided } 2(1-x) > \frac{1}{2} \end{cases}$$

A fixed point for  $H_2 \circ H_2$  for  $x \in (\frac{1}{4}, \frac{2}{2})$  is found by solving  $x^* = 2(1 - 2x^*)$ ; i.e.,  $x^* = \frac{2}{5}$ . Now  $H_2(\frac{2}{5}) = 2 \times \frac{2}{5} = \frac{4}{5}$  and  $H_2(\frac{4}{5}) = 2(1 - \frac{4}{5}) = \frac{2}{5}$ ; i.e.,  $\{\frac{2}{5}, \frac{4}{5}\}$  is a period-2 orbit.

4. (a) Consider the  $\mathbb{R}^1$  mapping  $x_{n+1} = F_\nu(x_n)$  where

$$F_\nu(x) = \nu x \exp(-x),$$

with  $\nu \in \mathbb{R}$ .

- Find all the fixed points of  $F_\nu$ .
- Determine the stability of the fixed points.
- Sketch the corresponding bifurcation diagram in the  $(\nu, x)$  plane. Indicate the stability of the fixed points on your sketch.
- Does  $F_\nu$  undergo subcritical flip bifurcations? Justify your answer.
- Does the iterated mapping  $F_\nu \circ F_\nu$  undergo subcritical flip bifurcations? Justify your answer. (Properties of the Schwarzian derivative presented in the lectures may be assumed).

(b) Consider the 2-dimensional continuous system governed by

$$\left. \begin{aligned} \dot{r} &= r(1 - r^2) \\ \dot{\theta} &= 1 \end{aligned} \right\},$$

where  $r(t) \in \Sigma$  and  $\theta(t) > 0$  are the time-dependent plane polar coordinates, and  $\Sigma$  is the open unit interval  $(0, 1)$ . The trajectory which starts at

$$\left. \begin{aligned} r(0) &= r_0 \\ \theta(0) &= 0 \end{aligned} \right\},$$

next crosses  $\Sigma$  at  $r_1$ .

i. Show that  $r_1$  satisfies

$$\int_{r_0}^{r_1} \frac{1}{r(1 - r^2)} dr = 2\pi.$$

ii. Hence find the corresponding Poincaré map  $P : \Sigma \rightarrow \Sigma$  such that  $P(r_0) = r_1$ .

**Solution.**

(a) i. Fixed points satisfy  $x^* = \nu x^* \exp(-x^*)$ . Clearly  $x^* = 0$  is a fixed point. For  $x^* \neq 0$  we have  $1 = \nu \exp(-x^*)$ ; i.e.,  $x^* = \ln \nu$  for  $\nu > 0$ . Therefore there are two fixed points:

$$\left. \begin{aligned} x_1^* &= 0 && \text{exists } \forall \nu \\ x_2^* &= \ln \nu && \text{exists for } \nu > 0 \end{aligned} \right\}.$$

ii. Stability of fixed points is determined by

$$F'_\nu(x) = \nu \exp(-x) - \nu x \exp(-x).$$

Then,  $F'_\nu(x_1^*) = \nu$  and  $F'_\nu(x_2^*) = \nu \exp(\ln \frac{1}{\nu}) - \nu \ln \nu \exp(\ln \frac{1}{\nu}) = 1 - \ln \nu$ .

Hence,  $x_1^*$  is stable for  $|\nu| < 1$  and unstable for  $|\nu| > 1$ . And  $x_2^*$  is stable provided that

$$\begin{aligned} -1 &< 1 - \ln \nu < 1 \\ \Rightarrow & 0 < \ln \nu < 2 \\ \text{i.e.,} & 1 < \nu < \exp(2) \end{aligned}$$

and unstable for  $\nu < 1$  and  $\nu > \exp(2)$

iii. Sketch: see figure 5.

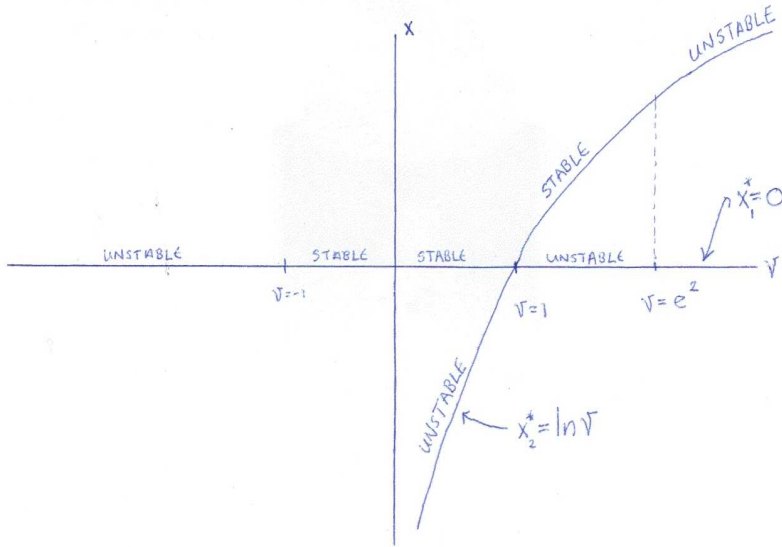

Figure 5:

- iv.  $F'_\nu(x) = -2\nu e^{-x} + \nu x e^{-x}$  and  $F''_\nu(x) = 3\nu e^{-x} - \nu x e^{-x}$   
 Schwarzian derivative:

$$\begin{aligned}
 D_s\{F_\nu\} &= \frac{F''_\nu}{F'_\nu} - \frac{3}{2} \left( \frac{F''_\nu}{F'_\nu} \right)^2 \\
 &= \frac{\nu e^{-x} (3-x)}{\nu e^{-x} (1-x)} - \frac{3}{2} \left[ \frac{\nu e^{-x} (x-2)}{\nu e^{-x} (1-x)} \right]^2 \\
 &= \frac{3-x}{1-x} - \frac{3}{2} \left( \frac{2-x}{1-x} \right)^2 \\
 &= \frac{-(x-2)^2 - 2}{2(1-x)^2} \\
 &< 0 \quad \text{for } x=0 \quad \text{and} \quad x = \ln \nu
 \end{aligned}$$

Therefore, there are no subcritical flip bifurcations.

Notice that for flip bifurcation at fixed point  $x = \ln \nu$ , we have:

$$F'_\nu(\ln \nu) = 1 - \ln \nu = -1 \Rightarrow \nu = e^2 \Rightarrow x = 2.$$

Therefore, the Schwarzian derivative is well-defined at  $x = \ln \nu$  (and obviously at  $x = 0$  too).

- v. Since

$$D_s\{(F_\mu \circ G_\mu)\}(x) = [G'_\mu(x)]^2 D_s\{F_\mu\}(G_\mu(x)) + D_s\{F_\mu\}(x),$$

for any three times differentiable  $F_\nu$  and  $G_\nu$  (a standard result proved in

class), it follows that  $D_s\{(F_\mu \circ F_\mu)\}(x) < 0$  and so there are no subcritical flip bifurcations.

- (b) i. Suppose the trajectory starting at  $(r_0, 0)$  next crosses  $\Sigma$  axis at time  $t = T$  ;  
i.e.,

$$\left. \begin{aligned} r(0) &= r_0, & r(T) &= r_1 \\ \theta(0) &= 0, & \theta(T) &= 2\pi \end{aligned} \right\}.$$

Then

$$\dot{\theta} = 1 \quad \Rightarrow \quad \int_0^{2\pi} d\theta = \int_0^T dt, \quad \text{i.e.,} \quad 2\pi = T$$

and

$$\dot{r} = r(1 - r^2) \quad \Rightarrow \quad \int_{r_0}^{r_1} \frac{dr}{r(1 - r^2)} = \int_0^T dt = 2\pi.$$

ii.

$$\begin{aligned} \int_{r_0}^{r_1} \frac{dr}{r(1 - r^2)} &= \int_{r_0}^{r_1} \left( \frac{1}{r} - \frac{1}{2(1+r)} + \frac{1}{2(1-r)} \right) dr \\ &= \left[ \ln r - \frac{1}{2} \ln(1+r) - \frac{1}{2} \ln(1-r) \right]_{r_0}^{r_1} \\ &= \left[ \ln \left( \frac{r}{\sqrt{1-r^2}} \right) \right]_{r_0}^{r_1} \\ \Rightarrow e^{2\pi} &= \frac{r_1}{\sqrt{1-r_1^2}} \frac{\sqrt{1-r_0^2}}{r_0} \\ \text{i.e.,} \quad \frac{r_1^2}{1-r_1^2} &= \frac{r_0^2 e^{4\pi}}{1-r_0^2} \\ \text{i.e.,} \quad \frac{1}{\frac{1}{r_1^2} - 1} &= \frac{e^{4\pi}}{\frac{1}{r_0^2} - 1} \\ \Rightarrow r_1 &= \left[ 1 + e^{-4\pi} (r_0^{-2} - 1) \right]^{-1/2} \\ \text{i.e.,} \quad P(r) &= \left[ 1 + e^{-4\pi} (r^{-2} - 1) \right]^{-1/2}. \end{aligned}$$
